Employee Attrition: Identifying the Reasons Behind Employee Turnover

The employee attrition is an important issue if the employees have a high turnover rate then it would lead to problems in the organisation like loss of organisational knowledge, increase in employee workloads, problems in team performance, and increased recruitment and replacement costs. Many organisations conduct employee surveys and exit interviews to identify employee turnover reasons. But these methods do not necessarily give a full and current view of the issues at hand.

One of the issues is organisations finding out about key employee issues at the point employees are making the decision to leave. Exit feedback can identify problems like career advancement, workload, management, salary, recognition, work environment, etc. But the data can be scattered among staff members, departments or time periods, and it can be hard to see trends or problems in the data. Based on the research and HR practice guidelines, exit interviews help an organisation to understand workplace problems and increase employee retention rates and enhance the overall employee experience. The issue isn't just that employees leave, it's that organisations can sometimes not have a systematic method to understand and identify new reasons for turnover before they begin to cause the staff to leave. Organisations need to better connect information from employees who have left with the experiences and concerns of the current employees.

Problem Statement

Organisations are challenged to identify factors leading to employee attrition at an early stage to understand the underlying causes and take timely remedial action for its effective redressal.

AI Incorporation

We're taking a different approach with our solution, leveraging AI as the main analytical engine that will analyze employee information and provide actionable insights. The AI system processes exit interviews from staff to find common issues and trends contributing to the attrition. The results of these findings are fed into the AI algorithm, which generates specific surveys to float around existing employees to identify if there are similar concerns. It then uses all this to determine which teams or departments are in danger (different levels of danger) and alerts the management. Last but not least, it recommends actionable, affordable retention tactics based on the current company practices and policies. In essence, AI performs a task that would otherwise take a lot of manual work and in this manner, companies can act proactively instead of reactively.
